Ethnicity and mental health: Conceptualization, definition and operationalization of ethnicity from a Canadian context

DE Clarke, PhD (1-4); A Colantonio, PhD (3-6); AE Rhodes, PhD (2,3,7-9); M Escobar, PhD (3)

Abstract

The current study provides a critical review of Canadian studies on ethnicity and mental health with respect to the definition, conceptualization and operationalization of ethnicity. It provides a discussion on the methodological issues related to these factors and their implications to guide future research and enable comparability of results across studies. Sociological Abstracts, PsycINFO, MEDLINE and CINAHL were used to identify relevant Canadian articles published between January 1980 and December 2004. The review highlights a number of key issues for future researchers to consider such as the need for: 1) clear rationales as to why ethnicity is important to their outcome of interest; 2) clarity on the definition of ethnicity, which affects its conceptualization and operationalization; 3) a theoretically driven conceptualization of ethnicity, which should be related to the research question of interest; and 4) clear rationales for the decisions made regarding the data source used, the operationalization of ethnicity, and the ethnic categories included in their studies.

Key words: ethnicity, ethnic origin, culture, race, mental health

Introduction

Canada’s immigrant population originates from all over the globe with increasing numbers from Africa, Asia, the Caribbean, and the Middle East (i.e. visible minorities). Its culturally diverse Aboriginal population adds to the ethnic mix. Canada prides itself on being a multicultural society by acknowledging the right of every person to identify with his/her cultural background while partaking in the Canadian way of life. This was advocated in its 1971 legislated policy on multiculturalism, which emphasized fair treatment of everyone, regardless of race, colour or ethnicity; particularly in terms of educational and occupational opportunities. Evidence of systemic inequalities, including access to educational and employment opportunities, housing, health and mental health care, are still evident across ethnic groups, which can impact the mental health of the population. For instance, Aboriginal peoples continue to have poorer mental health compared to the general population and, along with visible minorities, have ongoing difficulties accessing culturally sensitive mental health care. Better understanding of the relationship between ethnicity and mental health is compelling and highly relevant for policymakers and mental health practitioners in the Canadian context.

Canadian literature on ethnicity and mental health is quite limited despite its relevance. Much of the existing studies in this area were conducted in the United States (US) and the United Kingdom (UK), which has uncertain applicability to Canada. The political, social and economic ramifications associated with ethnicity or ethnic identity, likely differ from country to country. Differences in the countries’ ethnic compositions, histories of immigration policies and racism/slavery and ethnic or racial categorizations hinder cross-country comparisons. The history of slavery and segregation has a great deal of meaning for ethno-racial groupings in the US. Furthermore, the US is seen as a society that assimilates immigrants by the “melting pot” phenomenon, in which the immigrants are expected to adapt to the American way of life rather than retaining their culture. Canada has not had the same history of racial segregation and is viewed as a mosaic in which immigrants are encouraged to retain their unique cultural background while partaking in the greater Canadian society. Also, Latin Americans comprise a larger component of the US immigrant population than Canada’s.

The time of arrival and ethnic composition of the immigrant population in the UK and Canada also differ. Up to 1962, citizens of previously colonized countries such as Jamaica and India (countries that remained within the Commonwealth) were granted open access and actively recruited for...
immigration to the UK. During this time, Canada’s immigrant population came primarily from Europe, the UK and the US. Post-1971, when the UK changed its immigration act, the majority of its immigrant population originated from Europe and South Africa, while the majority of Canada’s immigrants came from Asia, Africa, the Caribbean, Latin America and the Middle East. These points indicate that results based on UK and/or US data might not be applicable to Canada.

With respect to the operationalization of ethnicity, variations exist across the literature on ethnicity and mental health. Lack of a clear definition of ethnicity and ongoing debate regarding how the variable should be conceptualized might account for this. Other factors such as data source used, feasibility, time period of data collection, region of study and sample size also affect the operationalization of the variable. To date, there is no seminal Canadian paper that discusses the methodological issues related to the definition, conceptualization and operationalization of ethnicity and their implications, to guide future research and to enable comparability across studies. This paper provides a critical review of the original empirical Canadian studies on ethnicity and mental health with emphasis on these issues. A general overview of the definition and conceptualization of ethnicity is first provided to guide the review process. Quantitative studies involving population-based data with more than one ethnic group are highlighted.

Methods

The bibliographic databases Sociological Abstracts, PsycINFO, MEDLINE and CINAHL were used to identify relevant original empirical studies that were quantitative in nature for this review with the application of Group 1 and 2 search terms outlined in Figure 1. Studies were included if they: 1) concerned ethnicity and mental health; 2) involved data on Canadians; 3) involved more than one ethnic group; 4) were published between January 1980 and December 2004; and 5) were quantitative in nature.

General review articles and chapters on the theories and definition of ethnicity, not specific to Canada, were used to provide an overview on the definition and conceptualization of ethnicity. As well, they guided the critique of the identified studies on ethnicity and mental health reviewed herein. Articles on ethnicity and immigration policies specific to Canada were used to provide historical context to facilitate understanding of the ethnic composition of the Canadian population over time and its impact on the studies reviewed.

Results

After all duplicates were removed, 49 empirical quantitative studies that involved two or more ethnic groups were identified and included in this review (Figure 1) and summarized in Appendix 1. Twenty-seven studies were based on population or community surveys with secondary data analysis, 12 were smaller studies using non-clinical samples and 10 were smaller studies based on clinical/specialized samples. The year and region of publication, sample size, ethnic groups included and critique regarding the definition of ethnicity are outlined in Appendix 1.

Discussion

1. Definition

The lack of consensus on the definition of ethnicity was reflected in the 49 included Canadian studies on ethnicity and mental health, which failed to explicitly define the variable. There are two major perspectives on how ethnicity emerges: the primordialist and constructivist views. Traditional primordialists view ethnicity as an ascribed status, given at birth, that is more or less fixed and permanent. Accordingly, the individual’s identity includes the biological, cultural, political and economic conditions of the group into which s/he is born, be it dominant over, or dominated by, other groups. A softer primordialist view stresses the social and non-biological basis of ethnicity, acknowledging that ethnic identity can also be socially constructed and based on “the circumstances at hand” thereby being “situational not biological” and “flexible not fixed.” The constructivists view ethnicity as “a social construction with ecological and social factors being its key determinants.”

2. Conceptualization

There are two major perspectives on how ethnicity is conceptualized: 1) ethnic identity which refers to self-identification with particular cultural group or ethnic origin which refers to classification due to the ethnic or cultural groups to which the individual’s ancestors belong. Specific cultural traits such as language, surnames, or region of birth were used as proxies for ethnic origin in some studies.

From a Canadian perspective, the country’s policy on multiculturalism, which has guided government policies since 1971 and advocated for individuals to retain their ethno-cultural background, dictates that ethnicity comprised “ethno-cultural particularism” and adherence to Canadian values. This is reflected in the conceptualization of ethnicity across national surveys, which forces participants to identify with their ancestral background regardless of time in Canada. As well, this policy accounts for the designation of all non-Aboriginal persons who originate...
FIGURE 1
Results of the search strategies used across bibliographic databases to identify Canadian literature on ethnicity and mental health

There was considerable overlap in the articles identified in the different bibliographic databases.

1 Group 1 search terms: 'ethnicity', 'race', 'ethno-racial', 'race/ethnicity', 'culture', 'ethno-cultural', 'visible minority', 'immigrants', 'aboriginal', 'First Nations', and 'Inuit or Méetis'

2 Group 2 search terms: 'mental health', 'psychological*', 'depression', 'psychiatric*', 'well-being', 'psychosocial', 'alcohol*', 'schizophrenia', 'substance abuse', 'suicide* and 'distress'

3 Note: * symbol attached to search terms was used to tell the search engine to find all articles containing the word or term.

4 Boldn indicates the quantitative empiric studies identified and included in this critical review.
Ethnic identity can be internal or external. Internal ethnic identity refers to the individual’s self-identification with specific ethnic group/s, which can be internally or externally driven. Individuals may choose to identify with particular ethnic group/s because of their belief in the customs, norms and ideologies of a particular culture, which can be internally or externally driven. Individuals may choose to identify with particular ethnic group/s because of their belief in the customs, norms and ideologies of a particular culture, which can be internally or externally driven. Since external ethnic identity relates to categorization by others based on the person’s nationality or ethnic origin and does not reflect the individual’s adherence to and/or identification with specific culture/s, it is discussed in the context of ethnic origin in the ensuing section. Such external assignment of ethnicities to individuals by the dominant society might conflict with their subscription and adherence to particular ethnic groups and is potentially distressing. This was illustrated by Mahtani in her interview with Canadian-born visible minority mixed-racial women who often feel forced by the ethnic majority to identify their ancestral background when asked about their ethnic identity (i.e. by the question, “but where are you from?”).

A major weakness with self-identification of ethnicity is that it is based on the individual’s perception, which may change from situation to situation and over time and likely produce different results depending on the time and research question being investigated. This possibly accounted for the lack of conceptualization of ethnicity based on external ethnic identity across studies, with the exception of the respective studies of De Wit et al., De Wit and Beneteau, and Feldman et al. conducted secondary data analysis on the 1990 Ontario Health Survey in which respondents were asked to select up to four ethnic categories that matched their “ethnic or cultural identity.” De Wit and Beneteau further utilized information on the primary language that respondents used at home to help “better identify ethnic groups.” If respondents identified French or French-plus other ethnic groups but did not select French as their primary language they were reclassified as Anglophones indicating externally driven classification of ethnic identity. This externally driven classification of ethnic identity might have been in conflict with the individual’s true ethnic identity. If level of adherence to particular cultural values, customs and ideologies are important in the individual’s perception of, and subsequent likelihood to acknowledge, discuss or report a mental health condition, and this is a key issue being investigated, then the use of ethnic identity would provide more appropriate information. Feldman et al. used the item, “Please write down the term that best describes the ethnic character of your everyday home environment,” which implies an ethnic identity conceptualization of the variable.

Ethnic origin refers to categorization of individuals into ethnic group/s based on ancestral origins. The question “To which ethnic or cultural group/s do your ancestors belong?” has been used to capture ethnic origin. This method of conceptualization was observed in some Canadian studies on ethnicity and mental health, particularly those that used national or regional survey data, including the National Population Health Survey (NPHS), Canadian Community Health Survey (CCHS), National Longitudinal Survey of Children and Youth (NLSCY), National Survey of Giving, Volunteering and Participating (NSGVP) and the 1971 Aging in Manitoba (AIM) survey. Each survey inquired about the ethnic or cultural group/s of the individuals’ ancestors and provided a list of ethnic categories to enable multiple choices. This acknowledged the existence of multi-ethnic groups, which are typical of Canada, and improved the reliability of the groups identified. Reflective of the emphasis of the country’s multiculturalism policy, survey respondents who identified themselves as “Canadian” were required to select their ancestral origin even if they were Canadian-born.

One might assume that studies utilizing data from surveys in which ethnicity was based on ethnic origin would conceptualize ethnicity accordingly; however, this was not the case. Ali and Ma used country of birth in thinking about ethnicity despite utilization of the CCHS and the NLSCY data respectively, both with specific ethnicity questions. The rationale for using country of birth rather than responses to the ethnicity questions was not provided but likely due to the use of public-use data. Public-use versions of Canadian national surveys are readily available to researchers.
but are stripped of unique identifying information and lack the detailed information on ethnicity and culture available in the restricted-use versions.

Penning32 utilized the Social Change in Canada Survey (SCCS) data, in which country of birth was used to determine ethnicity. Ascertainment of ethnicity based on country of birth in the study pinpoints an inherent limitation with conducting secondary data analyses where one has to make do with whatever variables are available. With this in mind, it is still important to mention that with increasing global industrialization and migration it has become inappropriate to use country/region of birth as the sole indicator of ethnicity. Individuals might have been born in one country to parents from another country, spent only a few years in that country and returned with their parents to the countries of their ancestral background thus choosing to identify with their ancestral culture. Therefore, country/region of birth, also utilized by Ali,3 Barnes et al.,35 Ma,45 Cohen and MacLean,31 Rousseau et al.,53,61 and Aubert et al.,65 would inaccurately classify such individuals. Most countries are comprised of many ethnic groups and most ethnic groups can be found to have many different countries of birth. Country of birth as a proxy for ethnic origin in some studies fails to capture such complexities and likely misclassifies some people. This does not negate the use of country/region of birth as a proxy for ethnicity but it underlines the need for detailed discussions of the inherent limitations of its use and implications for the interpretation of subsequent results.

Language and surname were proxies for ethnic origin in some studies but are susceptible to misclassification of some individuals. The utilization of surnames to identify ethnic groups by Dion and Giordano57 in their investigation of ethnic difference in depression in university students in Toronto, failed to correctly classify non-white/non-Caucasian individuals with non-ethnic last names. If specific ethnic groups were more likely to have individuals with non-ethnic surnames, for example Blacks from the Caribbean and South Asians of Christian descent,57 and these individuals were more or less likely to have depression, their exclusion would have biased the results obtained. Bagley60 also used surnames and language, but in combination with an unspecified “ethnicity” question to conceptualize ethnicity. Surnames were initially used to identify Chinese elderly persons living in Calgary, Alberta, with follow-up phone calls by the study recruiters who identified eligible Cantonese-speaking individuals and inquired about their ethnicity. This combination of factors overcame the shortcomings of using surnames alone.

Walter37 and Dion59 used language as a proxy for ethnicity, which might have accurately classified some ethnic groups but not others (e.g. Chinese for individuals who specified Chinese dialect). The English-speaking population is ethnically heterogeneous, with English being the primary language for many countries, so treating the group as homogenous is erroneous.59 Also, although French and Spanish are primary languages for France and Spain respectively, they are also the primary languages for some countries in the Caribbean and Africa. The assumption that all individuals who endorsed these languages are of European descent would be inaccurate.59 Different ethnic groups may speak the same language or there may be language differences within ethnic groups, which would not be captured with language as the sole proxy for ethnic origin.

Ethnicity, Race or Ethnicity plus Race

In examining the studies by Weekes, et al.71 and Cohen and McLean,38 respectively, it became apparent that categorization was based on race, despite the use of the term “ethnicity”. Also, the researchers implied that race and culture were the same concepts despite numerous theoretical articles indicating otherwise.58,76-79,85-99 To illustrate, Cohen and McLean utilized data from the 1999 General Social Survey (GSS) in which respondents were asked about their “cultural or racial backgrounds” and Weekes and colleagues expressed interest in examining the “cultural sensitivity” of their outcome scale. Ethnicity refers to mutual cultural characteristics such as religion, language, customs, and ancestry, but race refers to common physical characteristics.28,65,78,86-101 Winker,24 Williams37 and LaVeist37 stressed the importance of differentiating race from ethnicity or culture. Race is a poor proxy for ethnicity despite overlapping features and is questionable as its sole indicator in respective studies by Fry and Grover54 and Devins et al.74

Wu et al.2 used ethnic origin and racial background to create ethno-racial groups. This enabled the identification of visible minority groups and acknowledged the argument that power and status differences also exist across racial groups.77 This is important since “the dominant or minority status of the group reflects its position within the stratification system of the larger society,” which in turn affects access to social, political, and economic resources.3,4,101 The authors explained that their ethno-racial groups reflected the social stratification of the Canadian society (i.e. the vertical mosaic), which provided a context that facilitated interpretation of results obtained. The vertical mosaic refers to the hypothesis that ethnic groups are differentially integrated in the larger Canadian society based on histories of immigration policies that were linked to changing industrial and employment demands over time.2,4,7,8 This differential integration into the Canadian society affected the groups’ socioeconomic status, which is significantly associated with mental health outcomes.

Summary

The identified studies appeared to have conceptualized ethnicity on the basis of ethnic origin by using ethnicity questions, cultural traits as proxies for ethnic origin, or a combination of ethnic origin and racial background. For some studies, although the term “ethnicity” was used it was unclear how it was conceptualized and ascertained.30,33,34,54,55,70,75 The intrinsic weaknesses of using proxy measures such as country of birth, language or surnames underline the need for ethnicity to be ascertained using rigorously tested and validated questions. Questions aimed at
capacitating ethnic identity or ethnic origin are unable to tell which aspect of ethnicity the individual brings forward in response during an interview and whether this might be affected by the interviewer and/or by the specific question being asked. This highlights the need for clear and theoretically driven rationales for studying ethnicity across mental health outcomes.

3. Operationalization

The operationalization of ethnicity is important for interpretation of study results and enabling cross-study comparison. However, variations existed in the operationalization of ethnicity across studies. Even studies that utilized the same data sources and conceptualized ethnicity similarly operationalized the variable differently. Factors that influenced this included diversity of the study population, time period and region of data collection, sample size restrictions and purpose of the study. The effects of these issues are discussed in the ensuing sections.

Time Period of Data Collection and Study

Time period of data collection and study influenced the operationalization of ethnicity across studies. Time period of data collection is related to changes in the immigration policy over time, which were influenced by economic changes that dictated labour shortages and the need for immigrants to fill specific employment opportunities. Canada’s earlier immigration policy was based on national origin and gave preference to immigrants from Britain, Europe and the US to fill such occupational demands.

Hence, immigrants from these regions represented approximately 95% of Canada’s immigrant population up to 1986 and studies using data collected at this time had little or no representation of other ethnic groups.

The 1967 change to a universal point system was the force behind the increased ethnic diversity of the Canadian population, with European immigrants comprising 57% of immigrants in 1970 but only 20% in 1996. Changes in the ethnic composition of the immigrant population occurred gradually with small numbers from Africa, Asia, the Caribbean, Latin America, and the Middle East initially before their proportions increased significantly over time. This was reflected in the 3 to 5% representation of these immigrants in Canada up to the 1980s compared to their 73% representation between 1996 and 2001. Variations in the proportions of these immigrant groups relative to each other and to immigrants from Britain, the US and Europe were reflected in studies conducted with ethnicity data collected over the years. Earlier studies had little or no visible minority groups but their numbers increased in later studies. Whether these groups were kept as separate categories depended on the outcome of interest and the nature of the study (i.e. secondary data analysis using public-use data that lacked detailed ethnicity information). In the investigation of rare outcomes, such as some mental health conditions, small sample sizes for specific visible minority ethnic groups resulted in them being collapsed into a single category, which likely failed to capture the individuals’ perception of their ethnic identity. This also limited the interpretation of the results of such studies.

Region of Data Collection and Study

Variations in settlement patterns of different ethnic groups in Canada resulted in different ethnic compositions across geographic regions. This affected the operationalization of ethnicity as it relates to the region of data collection and study. Settlement patterns of immigrant groups have always been related to the location of employment opportunities, which were dictated by economic changes over time. Earlier immigrants from Britain, Europe and the US came to Canada in response to the rapid expansion of the Canadian West with integration of the region with the domestic and world markets and international demand for wheat. Therefore, many earlier immigrants settled in rural areas of Western Canada to fill the demands for laborers and farmers. Studies conducted in Western Canada (e.g. Manitoba, and the Northwest Territories) were likely to have significant representation of British, European, North American and Aboriginal ethnic groups but almost no representation of visible minority groups.

Later immigrants from Asia, Africa, the Caribbean, Latin America and the Middle East were more likely to settle in Montreal, Toronto and Vancouver because of their perception of better employment opportunities that corresponded to their skills and educational background. Supportive data showed that only 58% of recent immigrants settled in these areas in 1981 but the percentage rose to 78% by 2001. Recent studies based on data that includes these three regions had varying proportions of visible minority ethnicities. Reliance on public-use data prevented examination of very specific ethnic categories because of the inaccessibility of such detailed information.

The Purpose of the Research Study

As seen in the respective studies of Barnes et al., Lavallee and Bourgault, and others, there is flexibility in whether broad or specific categories are used when operationalizing ethnicity in descriptive or enumerative studies as long as they reflect the ethnic composition of the population under investigation. However, the use of specific ethnic categories is more informative. For analytic studies, operationalization of ethnicity needs to be theoretically driven to provide a framework for the analyses and interpretation of the results. Operationalization of ethnicity in the analytic studies reviewed in this paper appeared to be based on the social stratification system in Canada, though not always explicitly stated.

Studies interested in examining the mental health status or outcome in specific ethnic groups tended to be clear in their selection and ascertainment of those groups but often aggregated all other ethnic groups.
groups. For example, Fry and Grover were interested in examining mental health outcomes in Asians compared to Caucasians and therefore only included these groups. Liban and Smart, Tonkin, Beiser et al., Borzecki et al., Tcheng-Laroche and Prince and Dewit and Beneteau, in their studies, were mainly interested in the mental health of Native Indians and therefore only included these groups specifically while aggregating all other ethnicities in the comparison groups.

Havens and Chappell, in investigating the effects of age, sex and ethnicity on mental health in Manitoba, included North American, British, French, Polish/Russian/ Ukrainian and ‘Other European’ ethnic groups. These groups were reflective of the time period and region of study. North Americans, British and French were among the earlier immigrants admitted to Canada to fill occupational demands based on the country’s immigration policy at that time. The ‘Other European’ group, which included immigrants from Germany, Norway, Denmark, Sweden, Iceland, the Netherlands and Belgium, was granted entry into Canada over the Polish/Russian/ Ukrainian when the demand for more immigrants arose. After World War II and prior to the change to the universal points system immigration policy, immigrants from Poland, Russia, the Ukraine and other Eastern European countries were admitted to Canada to help survivors of the Nazi Holocaust and to fill specific occupational roles. Therefore, the ethnic groups included in the study were incorporated into the social hierarchy of Canada at different levels and different points in time, emphasizing the segregation of the Canadian society along ethnic lines. Aboriginal peoples also contributed to the ethnic diversity of Manitoba’s population, specifically its rural regions, but were excluded from the study to “reduce cultural bias”. This statement implied that cultural aspects of ethnicity were important in mental health functioning and needed to be kept constant across groups. It further implied that either the ethnic categories included in the study were culturally similar to each other yet different from Aboriginal peoples or that the individual ethnic groups that comprised each broader ethnic category were culturally similar but the individual ethnic groups that comprised the broader Aboriginal category were too culturally dissimilar to be combined.

Penning included similar ethnic groups as Havens and Chappell in examining the same hypothesis with psychosocial well-being as the outcome and using a nationally representative sample of Canadians aged 30 and over. The groups also mirrored the social stratification of the Canadian society. Havens and Chappell, but not Penning, found ethnic differences in mental health functioning with a “triple jeopardy” effect of age, sex and ethnicity. Methodological issues related to differences in the definition and ascertainment of the mental health outcomes, the conceptualization (e.g. use of country of birth versus a specific ethnicity question) and operationalization of ethnicity, the ethnic and age composition of the study populations, and the regions of study likely played a role in the discrepancy observed.

Since Penning used country of birth to ascertain ethnicity and mentioned no excluded ethnic groups, it is assumed that Aboriginal peoples and any Canadian-born visible minority individuals, though minimal, were included into the Canadian group. This would make the Canadian group heterogeneous and different from those included in the North American group in Havens and Chappell. Also, since Penning utilized data from a national survey, the ethnic category ‘Other’ probably comprised participants who were members of Canada’s visible minority groups whereas these groups were excluded by Haven and Chappell because of small sample size. Penning separated Canadians and Americans while combining immigrants from France, Germany, Norway, Denmark, Sweden, Iceland, the Netherlands and Belgium into a Northern European group. These factors affected the ability to compare the results of the two studies.

Understanding the mental health of Canada’s immigrant population in terms of depression and alcohol dependency was the aim of the study by Ali. Ethnic differences were examined as a secondary objective in the immigrant group only. Using region of birth, the ethnic groups examined (i.e. US/Mexico, South and Central America and the Caribbean, Europe, Africa and Asia) mirrored the variation in time of entry into Canada by the different immigrant groups and their differential incorporation in the social hierarchy of the country. This provided a framework for analyses and interpretation of the results. Disaggregation of only the immigrant group based on ethnicity implied that either the investigation of ethnic variation in mental health was only important for immigrant groups and not Canadian-born or all Canadian-born individuals had similar experiences that potentially affected their mental health. Since the Canadian-born group probably had many first generation Canadians who likely had similar experiences as their immigrant parents, these assumptions were likely inaccurate. Given the report of poor mental health in Canada’s Aboriginal population, combining them into the Canadian-born group might not be appropriate. The use of region of birth has numerous drawbacks that could have potentially biased the results obtained but was likely used because of the lack of ethnicity-related information in the public-use version of the CCHS Cycle 1.1 dataset, which is assumed to be the data source used by Ali.

In examining behavioural and emotional problems in immigrant versus non-immigrant children in Canada, considered ethnicity relevant but only for the immigrant group. Immigrant children were disaggregated into ethnic groups based on region of birth, including those from the US, Europe, Asia and other regions possibly due to the use of the
public-use version of the NLSCY. These ethnic categories differed from Ali’s despite
the same method of conceptualizing ethnicity. The studies tested different
hypotheses, and were interested in different populations and different outcomes, which
affected the ability to compare results across studies.

Beiser et al. utilized NLSCY data to examine familial poverty and emotional
and behavioural problems in immigrant children versus Canadian-born and included
ethnicity as a control variable. Unlike Ma, ethnicity was examined in the entire
sample thereby eliminating the ambiguities observed in interpreting the results of the
former studies. Although the study utilized a data source in which various ethnic
categories were available, ethnicity was operationalized by using four broad
categories including White/European, Asian, Black and Other. This implied an
interest in, or expectation of, an effect based on visible minority status. The NLSCY
included Aboriginal peoples living off-reserves, and since there was no explicit
indication of their exclusion, it is assumed that they were either combined in the
‘Other’ category or included in the ‘White/European’ category. The appropriateness of
the inclusion of Aboriginal children into either category is questionable given major
cultural and social differences.

The NSGVP was utilized by Mata to examine social support resources.

The distinction between certain other ethnic categories was unclear. For instance, the categories
definite European origin were used without the provision of a clear rationale. This
combination of specific and broad ethnic
categories without rationale limited the
interpretation and comparability of the results. It would have been beneficial if the ethnic categories were guided by a
theoretical framework so as to provide
more meaning to the results and decrease the observed ambiguity.

Wu et al. tested the hypothesis that ethnic differences in depression could be explained by variations in SES and access to social
support resources (1996 NPHS data). The included ‘ethno-racial’ groups were ‘East/
racial’, were “representative of the social
stratification of the Canadian society” and
reflected differences in SES and access to social support resources. The partial
disaggregation of the Asian group into
‘East/Southeast Asian’ and ‘Chinese’ was
likely due to the overwhelming presence of ‘Chinese’ (approximately 56%) in the
group, which would have obscured the
interpretation of any association with depression. A clear rationale for this partial
disaggregation was not provided but left to
the readers to assume. Lack of sufficient sample size prevented the disaggregation of other ethnic groups including Blacks and South Asians.

Wang and El-Guebaly used a ‘White’
versus ‘non-White’ dichotomy in
operationalizing ethnicity despite the
utilization of the 1996 NPHS data. This
was likely due to the use of the public-use
version of the survey data, though not
explicitly stated. This dichotomy, although
handy in separating visible minorities from
the ethnic majority, has been criticized for
its inadequacy in giving a clear view of
ethnic differences in mental health. Refinement is needed to account for
cultural and/or ecological differences within such broad ethnic groups, which
might include cultural biases in reporting mental health issues. Although the specific
ethnicities within the broad ‘non-White’
group are distinct from each other in
languages, histories, customs and social
mobility, discrimination in educational
and occupational opportunities based on
visible minority status lends some
support to combining the groups into this
category. The use of such a broad ethnic
category is appropriate if the researchers
were asserting that it is the common
experience of being ‘non-White’ that
impacts mental health above and beyond
the effect of cultural differences in
individuals’ perceptions of, and attitudes

Dion and Giordano included ‘Anglo-
Celtics’, ‘North European’, ‘South
European’, ‘East European’, ‘East Asian’,
and ‘South Asian’ in their study. These
ethnic groups were said to parallel the
ethic composition of the University of
Toronto population in 1988 and reflected
variations in immigration experiences,
entrance status and adaptation to life in
Canada with respect to parental conflicts,
and the likelihood to perceive economic
discrimination. According to the study,
‘South Asians’ and ‘Southern Europeans’
were more likely to suffer depression than the ‘Anglo-Celtics’ and ‘Northern
Europeans’ because of higher likelihood of
parental conflict and perceived economic
discrimination. Surnames were used to
ascertain ethnicity, which likely
misclassified ‘Blacks’ and ‘South Asians’
of Christian background. Since ‘South
Asian’ was an ethnic group of interest in
the study, this misclassification would
have likely affected the results obtained by
diluting the measure of effect and affected
the generalizability of the results to all
‘South Asians’ in Toronto. The researchers explained that since an earlier study
including 300 students at the same
university found less than 3% indicating
West Indian heritage, the potential
misclassification by surnames created little
or no bias to their results. This inaccurately
implied that among ‘South Asians’ only
those of West Indian heritage had non-
ethnic last names. India’s Christian
population accounted for about 2.3% of its
total population according to its 1991 and
2001 censuses.

Summary
In summary, the operationalization of
ethnicity in the existing Canadian studies
differed depending on how the variable
was conceptualized, on which data sources were used, on time period and region of data collection, the purpose of the study, and whether the study involved secondary data analysis using public-use versions of national surveys. Some studies tried to disaggregate ethnic categories but were faced with sample size limitations that led to collapsing of distinct ethnic groups while keeping others disaggregated, with no clear rationale. Sample size limitations were found across national survey datasets, particularly for the visible minority ethnic groups, thus underlining the need for future population surveys aimed at providing information on the health and/or mental health of the Canadian population to over-sample these groups. This would enable the examination of mental health differences across visible minority groups, which is important for the planning of mental health programs to serve Canada’s ethnically diverse population.

Conclusions

This critique of the definition, conceptualization and operationalization of ethnicity across Canadian studies on ethnicity and mental health uncovered a number of key issues that are highlighted below.

a) Ethnicity is a complex and abstract term for which a single and generally accepted definition has not been derived. However, the underlying theme is that it involves the sharing of a common culture. Across studies, ethnicity was not defined a priori, which was likely due to lack of consensus on its definition. Therefore, as suggested by reviewers from the US\textsuperscript{26,77,79} and UK\textsuperscript{27,92,93} clear rationales as to why ethnicity is important to the outcome of interest are necessary.

b) Examination of the relationship between ethnicity and mental health needs to be encouraged with better infrastructure involving improved funding opportunities, given the relevance to the Canadian context. Secondary data analysis is valuable in such research efforts. Therefore, making detailed information on ethnicity more readily available to researchers while maintaining survey participants’ confidentiality is vital.

c) Some researchers seemed to have utilized public-use versions of survey data, which hindered their ability to disaggregate ethnic groups due to lack of such detailed information in these files. Their use need to be stated explicitly and their inherent limitations discussed.

d) Ethnicity can be conceptualized based on \textit{ethnic origin}, \textit{ethnic identity}, or a combination of ethnic origin and race. Each method has strengths and weaknesses. Its conceptualization should be theoretically driven and related to the research question of interest. The identified studies conceptualized ethnicity based on \textit{ethnic origin}, whether through the use of a specific questions or proxy measures such as language, surname or country of birth. Countries of birth, language and surnames are prone to misclassification of certain ethnic groups and biased results if rate of misclassification differed across outcome groups. This does not negate their use as proxies for ethnicity; however, there is a need for researchers to clearly outline their inherent limitations and the implications for the results obtained.

e) Ethnicity based on \textit{ethnic origin} can be more stable if participants are given a list of ethnic categories with the option of choosing multiple categories.\textsuperscript{27,93} This list should be based on preliminary fieldwork to identify common ethnic categories. An open-ended ‘other’ option should be included so as not to restrict the individuals’ choices. The list should be appended to the research results or made available upon request to enable study replication and to enable readers to ascertain the representativeness of the ethnic categories to the general population.

f) Operationalization of ethnicity varied from very broad to very specific ethnic categories even if ethnicity was conceptualized similarly or the same data source was used. These variations were related to the lack of a clear definition of ethnicity, differences in the time period, region of study and data collection, the purpose of the studies and the utilization of public-use data. Researchers are encouraged to provide a clear outline of the decisions made regarding the data source used (particularly in secondary data analysis), the operationalization of ethnicity, and the categories included in their studies. This will facilitate the interpretation of the results and attempts to replicate the research findings.

g) Differences in the outcomes of interest, how such outcomes were measured and variability in the relevant variables controlled for were additional factors that affected the ability to compare results across studies. Therefore, researchers should clearly define their outcomes of interest and summarize the strengths and weaknesses of the measures used to ascertain outcomes and other relevant variables.

Acknowledgements

Diana E. Clarke is a Research Associate in the Department of Mental Health at Johns Hopkins Bloomberg School of Public Health and Fellow in Population Health Studies in the Department of Psychiatry at University of Toronto. Dr. Clarke is supported by a Canadian Institute for Health Research Post-doctoral Fellowship Award (Grant # 200602MFE-159564-115967), the Toronto Rehabilitation Institute Foundation and in part by the Population Health Fellowship Award from the Department of Psychiatry at the
University of Toronto. This study was funded in part by the Ministry of Health and Long-term Care and the Ontario Mental Health Foundation.

2. Ethnicity based on ‘country from which the individual’s ancestors on the male side came when they settled in Canada’, therefore an ethnic origin conceptualization.  
3. Ethnic groups reflective of the immigration pattern in Canada during the time period (i.e. 1960’s) |
| 2. Liban & Smart, 1982 (Ontario, Canada)        | N = 128, A = 10 to 20 (i.e. Grade 7 to 13), S = 1979 Survey of Alcohol and Drug Use among Ontario students, D = Cross-sectional, DA = Descriptive and Chi-square analyses | Native Indian [64], Non-Native Indian [64] | DV: Frequency and problems with alcohol and drug use | 1. A clear definition of ethnicity not given.  
2. Ethnicity based on cultural background but how ascertained not specified.  
3. Although cultural background in the survey included a breakdown into English Canadian, French Canadian, Asian, Native Indian and other, the non-Native Indian categories were aggregated for the study based on matching |
| 3. Havens & Chappell, 1983 (Manitoba, Canada)    | N = 3647, A = 65+, S = Aging in Manitoba Survey (1971), D = Cross-sectional, DA = ANOVA | North American [370], British [1633], French [216], Polis/Russian/Ukrainian [685], Other European (German, Norwegian, Danish, Swedish, Icelandic, Dutch, Belgian) [743] | DV: Perceived well-being, perceived health status, mental health functioning | 1. The ethnic groups in the study not representative of the whole of Canada but of Manitoba specifically.  
2. Ethnic groups reflective of the immigration pattern in the province and of the time period.  
3. Ethnic origin based on ethnicity question in the survey |
| 4. Penning, 1983 (Canada)                        | N = 2253, A = 30+, S = Social Change in Canada Survey (1977), D = Cross-sectional, DA = ANOVA | Canadian [1720], American [57], British [159], North European (France, Germany, Austria, Scandinavia, Netherlands) [96], South European (Greece, Portugal, Spain, Italy) [65], East European (Russia, Hungary, Poland) [96], Others [62] | DV: Perceived psychological well-being | 1. A clear definition of ethnicity not given.  
2. Some ethnic categories not clearly explained for example the ethnic group referred to as ‘Other’.  
3. Ethnic origin based on country of birth |
2. Study interested in examining ‘cultural effects’.  
3. Study included French- and English-Canadians in Montreal. It is unclear how being French and/or English-Canadian were ascertainment |
| 6. Tonkin, 1984 (British Columbia, Canada)       | N = 122, A = < 20 years old, S = Vital statistics data (with follow-up review of all deaths reported to the provincial Chief Coroner’s office 1978/9), D = Cross-sectional, DA = Descriptive and chi-square analyses | Native Indian [33], Non-Natives [89] | DV: Suicides and psychiatric diagnoses | 1. A clear definition of ethnicity not given.  
2. Ethnicity used as a covariate but how it was ascertainment not indicated because it was abstracted from the coroners’ records.  
3. The rationale for the inclusion of ethnicity as a covariate not explained |
| 7. Barnes et al., 1988 (Winnipeg, Manitoba, Canada) | N = 524, A = 18 to 80, S = 1983 Winnipeg Area Study, D = Cross-sectional, DA = ANOVA, X2, B multiple classification analyses | English [84], East European [62], West European [82], Canadian [193], Other [97] | DV: Depression (CES-D) | 1. Ethnicity examined as a predictor of depression.  
2. Ethnic groups reflective of the ethnic composition region of study.  
3. Ethnic origin based on country of birth |

| 8. Sack et al., 1993 (Canada & US)³⁶         | N = 1115  
A = 7 to 9 (Grades 2 and 4)  
S = Flower of Two Soils Project  
D = Prospective and longitudinal (3 year follow-up)  
DA = Correlation analyses, ANOVA, chi-square analyses  
T = Analytic  
| First Nation children from the Plains (South Dakota, US), Northern Woodlands (Manitoba, Canada), Desert (New Mexico, US) and Coastal (British Columbia, Canada) compared to a sample of non-Native children at each site  
| DV: Depressive symptoms using new measures of psychopathology and mental health (the SOS)  
| 1. No explicit definition given for ethnicity.  
2. Study specifically interested in cultural differences between the various First Nation groups across North America, hence it is implied that ethnicity is based on culture. |
| 9. Walters, 1993 (Hamilton, Ontario, Canada)³⁷ | N = 356  
A = 21+  
S = A stratified random sample of women in Hamilton  
D = Cross-sectional  
DA = Chi-square  
T = Descriptive  
| English-speaking vs. other language  
| DV: Stress, anxiety and depression  
| 1. Ethnic origin based on primary language.  
2. No definition for ethnicity.  
3. Language stated as a possible proxy for ethnicity. |
| 10. Beiser et al., 1994 (Vancouver, British Columbia, Canada)³⁸ | N = 1667  
A = 7  
S = 1348 refugees from the Refugee Resettlement Project and an area-probability sample of 319 Vancouver residents matched to refugees on age and sex  
D = Cross-sectional  
DA = Grade of Membership analysis (GOM: a multivariate clustering technique)  
T = Analytic  
| Southeast Asians [1348];  
Resident Canadians [319];  
Southeast Asian group disaggregated: Chinese [755], Vietnamese/Lao [593]  
| DV: Psychiatric disorders including depression, anxiety and somatization per the CES-D, DIS and the Senegal Health Scales  
| 1. No explicit definition given for ethnicity.  
2. Researchers interested in ‘psychopathological expression among different ethno-cultural groups’, therefore ethnicity based on culture.  
3. Ethnicity based on where the individual emigrated from. |
| 11. Beiser et al., 1998 (Canada & US)³⁹ | N = 1708  
A = 7 to 9 (Grades 2 and 4)  
S = A native Ontario Community Survey and the Mental Health Supplement of the Ontario Health Survey  
D = Cross-sectional (but age at onset information used to look at incidence)  
DA = Descriptive and chi-square and survival analyses  
T = Analytic  
| First Nation children from the Plains (South Dakota, US), Northern Woodlands (Manitoba, Canada), Desert (New Mexico, US) and Coastal (British Columbia, Canada) [1251] compared to a sample of non-Native children at each site [457]  
| DV: Depressive symptoms using new measures of psychopathology and mental health (the SOS)  
| 1. No explicit definition given for ethnicity.  
2. Study specifically interested in cultural differences between the various First Nation groups across North America. |
| 12. DeWit et al., 1999 (Ontario, Canada)⁴⁰ | N = 4531  
A = 19+  
S = A stratified random sample of women in Hamilton  
D = Cross-sectional  
DA = Occupation and industry, age, and education  
T = Analytic  
| Native Indian [876],  
Non-Natives [3655]  
| DV: Alcohol drug use and onset  
| 1. No explicit definition given for ethnicity.  
2. Study specifically interested in cultural differences between Native Indians and non-Natives in Canada. |
| 13. DeWit and Beneteau, 1999 (Ontario, Canada)⁴¹ | N = 5150  
A = 16+  
S = A stratified random sample of women in Hamilton  
D = Cross-sectional  
DA = Occupation and industry, age, and education  
T = Analytic  
| Anglophone [4023],  
Francophone [1127]  
| DV: Alcohol consumption (i.e. frequency and volume); alcohol-related problems (i.e. driving under the influence, family conflicts, work conflicts, sought help for drinking, hospitalization for drinking, and/or arrested for drunk behaviour)  
| 1. No explicit definition of ethnicity given.  
2. Ethnicity based on a combination of ethnic identity and primary language used at home. |
| 14. DeWit and Beneteau, 1999 (Ontario, Canada)⁴² | N = 5150  
A = 16+  
S = A stratified random sample of women in Hamilton  
D = Cross-sectional  
DA = Occupation and industry, age, and education  
T = Analytic  
| Anglophone [4023],  
Francophone [1127]  
| DV: Daily tobacco consumption (i.e. frequency and volume)  
| 1. No explicit definition of ethnicity given.  
2. Ethnicity based on a combination of ethnic identity and primary language used at home. |
| 15. Feldman et al., 1999 (Toronto, Ontario, Canada)⁴³ | N = 1236  
A = Grade 9 to 13 students  
S = A stratified random sample of women in Hamilton  
D = Cross-sectional  
DA = Descriptive analyses, stratified analyses and multiple logistic regression analyses  
T = Analytic  
| Canadian [379],  
European [277],  
Asian [314],  
Other [140],  
Not stated [126]  
| DV: Alcohol use beliefs and behaviour  
| 1. No definition given for ethnicity.  
2. ‘Please write down the term that best describes the ethnic character of your everyday home environment’ was used to ascertain ethnicity indicating an ethnic identity conceptualization. |
